TITLE

PROGRAMS FOR STORAGE MANIPULATION
AND CALCULATION OF DATA USING DECTAPE

AUTHOR

D. Eugene Hokanson

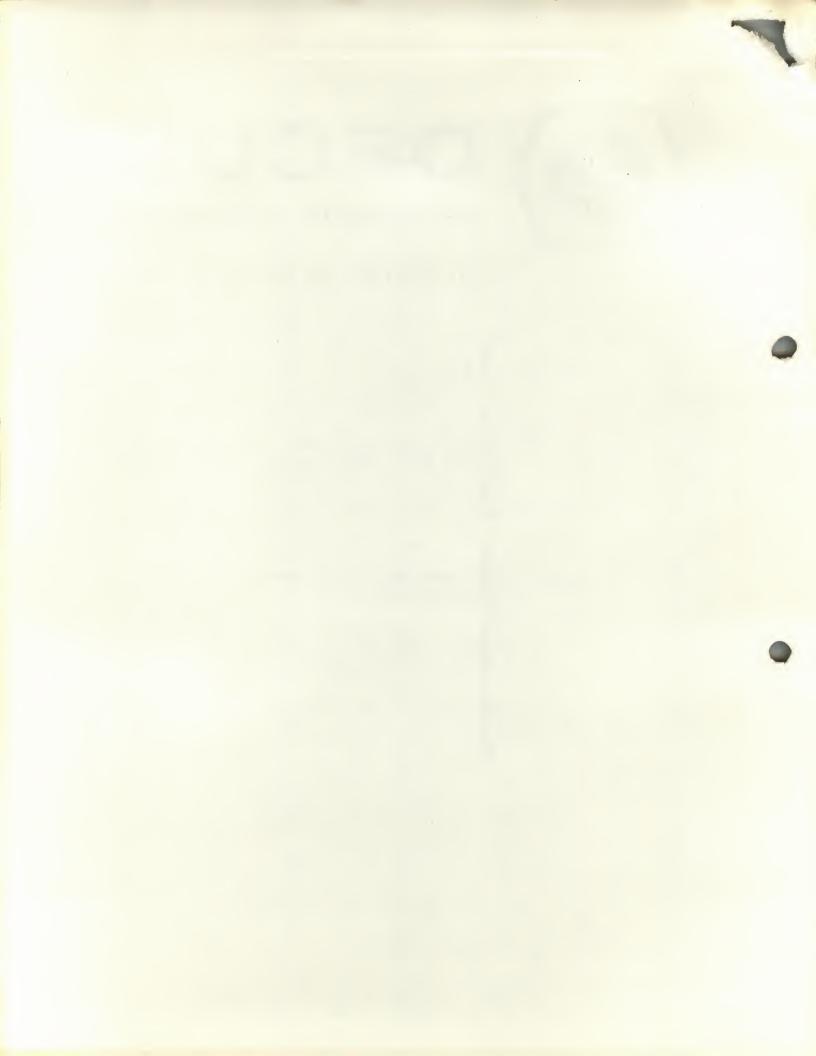

COMPANY

Veterans Administration Hospital Seattle, Washington

DATE

July 2, 1968

SOURCELANGUAGE

DECUS Program Library Write-up

DECUS No. 8-137

INTRODUCTION: These programs use DECtape for the storage of data files. Once data has been stored on DECtape, the statistical or calculation programs will operate on particular parts of it selected by the user. All programs are conversant. They ask questions regarding execution and accept answers via the teletype.

Tape unit #1 is used for data tape. Data tapes may be formatted in standard (12910) or shorter block lengths. Data is stored and operated on in floating point. Data files may be complete or partial blocks of tape. Each file is terminated by a "\$" (244) on DECtape. Up to 42 numbers may be stored on one block of standard data tape.

GENERAL OPERATING INSTRUCTIONS: Programs which have the capability of writing on data tape will first query the user about data tape format. Standard data tapes have (12910) computer words per block. All questions requiring yes or no answers are answered by typing "Y" or "N". The floating point input subroutine is used for all inputs so all number answers to questions are in decimal.

Line or block numbers may be input singly or successively and input is terminated by typing "CTRL/FORM". An example is:

BLOCK NUMBERS: 10 23,27 50 (CTRL/FORM typed here)

This would cause the program to read data in blocks 10, 23, 24, 25, 26, 27, and 50.

The only exception to this is in FORT where the last group of block numbers is terminated by typing "\$".

After execution of a program, the character CTRL/C (+C) will return control to the Monitor so the mext program can be called. Use of this feature enables the user to make a control paper tape which contains program calls and the appropriate answers and commands for execution so that long periods of unattended data processing are possible.

SUBROUTINES: SUBS is a package of four subroutines used by most of these programs. SUBS contains six pointers on page zero and subroutines in the area from 4000 to 7577.

These subroutines are:

MESSAGE	<4000,4057>	Type packed text
UNFLOAT	<4100,4130>	Unfloat floating point numbers
RWTAPE	<4200,4342>	Read and Write DECtape
FPOINT	<4400,7577>	Floating point Output Controller

The pointers are:

0002	4200	/RWTAPE
0003	4000	/MESSAGE
0004	4100	/UNFLOAT
0005	7400	/FPOINT Input
0006	7200	/FPOINT Output
0007	5600	/FPOINT Arithmetic Interpreter

FLEX is an extended version of Floating Point which lacks the Output Controller. It is used to overlay the FPOINT section of SUBS in the programs which use extended Floating Point.

LISTINGS: Source programs are furnished as symbolic files on DECtape. In order to compile one of the programs it is necessary to create one file which is composed of several symbolics for use with XPAL. SUBS should be called before using XLOAD to load the Pass 2 output of XPAL. The resulting program is updated including the area used by SUBS.

Three programs, LCOVAR, BCALC AND LCALC, use extended Floating Point without the Output Controller (FLEX). The procedure to initially load one of these programs is to call SUBS, then FLEX, and then XLOAD the Pass 2 of XPAL.

The source programs are made up of the following symbolic files in order:

DATRIT = DATA WRITE

PURPOSE: This is a program to write data on DECtape directly from the ASR-33. Numerical data is stored on DECtape in floating point format and a "\$" (244) is written immediately following the last data point to signify the end of data in each block of tape.

OPERATION: The program will query the user about the format of the data tape mounted on unit #1. Next, the program asks "START AT BLOCK: " and the user types the block number (decimal) of the first data block to be recorded.

At this point the program waits for data input. Only valid floating point inputs are accepted; illegal characters are ignored. Up to 42 floating point numbers and the terminating "\$" may be recorded on a block of standard data tape. After the input of the maximum number of data points (42 for standard data tape), data will automatically be recorded in the starting block number previously specified. Successive data will be recorded in successive blocks.

CONTROL CHARACTERS:

\$ If less than the maximum number of data points per block are to be recorded the input of a "\$" will terminate data input for that block and cause recording of data up to

the "\$". Next data will go in the next successive block.

- / This character causes the program to type the block number of the next data block to be recorded,

 "NEXT BLOCK = nn ".
- # This character is used if data is not to be recorded in successive blocks of data tape. It causes the program to return to "START AT BLOCK: ".

CTRL/C Return to tape Monitor.

EDATA - EDIT DATA

PURPOSE: This is a program to edit data files created on DECtape by DATRIT.

OPERATION: The program will query the user about the format of the data tape mounted on unit #1. After that, the teletype bell will ring and EDATA waits for a command from the user. This program uses a core buffer to store the data file being edited.

The following commands are possible in EDATA:

R 2 READ		This command causes the program to type
		"BLOCK NUMBER: ". The user types the block
		number (in decimal) of data tape to be read.
		READ destroys data previously in the buffer
		by reading in over it.

RA 2	READ APPEND	This command is similar to READ. Data read in
		prior to RA will be retained and data in the
		new block will append the original. If there
		is more data in the new block than can be added
		to data already in the buffer, "OVERFLOW" will
		be typed and the buffer is left unchanged.

Z	WRITE	This command causes the program to type
		"BLOCK NUMBER : ". The user types the block
		number (decimal) of tape on which data in the
		buffer will be written. The buffer is not
		affected by this command.

D	DELETE	This command deletes all data in the buffer.
La	LIST	This command causes the program to list all
		the data in the buffer.

EDATA = EDIT DATA (continued)

12	SLASH	This command causes the program to type "LAST DATA AT nn" where nn indicates the total number of data points in the buffer.		
nL ₂	LIST	This command causes the program to list data point n.		
n,mL2	LIST	This command causes the program to list data points n through m inclusive.		
nD 2	DELETE	This command causes the program to delete data point n.		
n,mD2	DELETE	This command causes the program to delete data points n through m inclusive.		
nC 2	CHANGE	This command causes the program to change data point n. Additional data points (after the first which replaces point n) are added after n. After the desired changes are completed, this command must be terminated by "CTRL/FORM".		
nI 2	INSERT	This command causes the program to insert data point n. Similar to CHANGE - after this command data is typed in to be inserted starting at point n. Data inserted will appear before the data point previously at n. This command must be terminated with "CTRL/FORM".		
A 2	APPEND	After this command, data is accepted to be added after data already in the file. This command must be terminated by "CTRL/FORM".		

EDATA = EDIT DATA (continued)

CTRL/C

This command returns control to the tape Monitor.

The commands CHANGE, INSERT, and APPEND terminate automatically when the buffer becomes full and the program types "BLOCK FULL".

An error in the format of a command causes the program to type "??" carriage return, line feed.

After the completion of any command, the bell will ring and the program waits for a new command.

SDT = STANDARD DEVIATION

PURPOSE: This is a program to calculate Mean and Standard

Deviation from data files stored on DECtape data tape.

The output consists of:

- 1. Sample Size N.
- 2. Sample Mean.
- 3. Sample Variance.
- 4. Sample Standard Deviation.
- 5. Standard Error of the Mean.

OPERATION: When SDT is called, it will type "READ LINES: ".

The user may input specific lines of data blocks and terminate this input with "CTRL/FORM" or he may type "A" for all if complete data files are to be used. The program will then ask "BLOCK NUMBERS: " and the user should input block numbers terminated by "CTRL/FORM".

After the input of block numbers, the program will proceed through calculation and output, and return to "READ LINES: " unless this request has previously been answered by "A" in which case the program will start at "BLOCK NUMBERS: ".

DESCRIPTION: SDT will accommodate data tapes with standard length (129_{10}) or shorter block length since it reads standard length blocks and takes the "\$" as the end of a data file.

SDT is a two-pass program. On the first pass, data is summed and counted. The Mean is calculated before pass 2. During pass 2 the Sum of Squared Deviations from the Mean is computed. This is the most accurate method of computation for large numbers of large data. The program reads data tape in order (from the smallest block numbers to the largest during pass 1, and from the largest to the smallest during pass 2) so as to minimize tape spinning.

SDT = STANDARD DEVIATION (continued)

Calculations used in this program are as follows:

the number of data points operated on.

$$MEAN = \frac{\Sigma \times X}{N} = \overline{X}$$

SAMPLE VARIANCE =
$$\frac{\Sigma (x - \overline{x})^2}{(N-1)}$$

SAMPLE STANDARD DEVIATION =
$$\frac{\sum (x - \overline{x})^{2}}{(N - 1)}$$
STANDARD ERROR of MEAN =
$$\frac{\sum (x - \overline{x})^{2}}{(N - 1)}$$

STANDARD ERROR of MEAN =
$$\frac{\sqrt{\sum (x - \bar{x})^2}}{(N-1)}$$

FORT = F OR T ANALYSIS OF VARIANCE

PURPOSE: This program calculates an analysis of variance table similar to DECUS NO. 5/8-9 using data files stored on DECtape data tape. The output is:

- A. For each sample
 - 1. Sample size
 - 2. Sample mean
 - 3. Sample variance
 - 4. Sample standard deviation
- B. Grand Mean
- C. Analysis of Variance Table
 - 1. Total sum of squares of deviations from the grand mean
 - 2. Total degrees of freedom
 - 3. Total variance
 - 4. The pooled sum of squares of deviations of sample values from sample means
 - 5. Degrees of freedom within groups
 - 6. Variance within groups
 - 7. Weighted sum of squares of sample means about the grand mean
 - 8. Degrees of freedom between samples
 - 9. Variance between samples
 - 10. F, the ratio of the variance between samples to the variance within samples if there are more than two groups of inputs
 - 11. T, the square root of F in case there are only two groups input

FORT = F OR T (continued)

OPERATION: When called FORT will type "READ LINES: ". The user will answer by typing line numbers of data to be operated on terminated by "CTRL/FORM". The user may reply to "READ LINES: " by typing "A" indicating all. In this case FORT will read complete data blocks instead of selected lines. Once the instruction "A" has been given the program will only demand "BLOCK NUMBERS: " unless the program is restarted.

After "READ LINES: " FORT will type "BLOCK NUMBERS: ". The user then types the block numbers of blocks on data tape containing the desired data terminated by "CTRL/FORM" with the exception that the last group of block numbers is terminated by "\$". After completion the program will restart at "READ LINES: " unless this request has been answered by "A" in which case the program will restart at "BLOCK NUMBERS: ".

DESCRIPTION: FORT will accommodate data tapes with standard (12910) or shorter block length. After each set of line and block numbers FORT performs an ordered, two pass calculation of Sample Mean, Variance and Sample Standard Deviation similar to that done by SDT. A cumulative sum and count of data points is kept so that the Grand Mean is calculated immediately after the last sample input. A third pass of the data tape is done in which all data blocks are read in order of increasing block numbers and the Grand Mean is subtracted from each data point in order to calculate the total sum of squares of deviations from the Grand Mean.

FORT = F OR T (continued)

Calculations performed by this program are as follows:

A. For each sample

- 1. Sample size = N or Nsample
- 2. Sample mean = $\frac{\Sigma \times N}{N} = \bar{x}$
- 3. Sample variance = $\frac{\Sigma(x-\bar{x})^2}{N-1}$
- 4. Sample standard deviation $= \sqrt{\frac{\sum (x \bar{x})^2}{N-1}}$
- B. Grand Mean = $(\frac{\sum x}{N})$ Total = \bar{x}_G

C. Analysis of Variance Table

- 1. Total sum of squares = $\Sigma(x \bar{x}_G)^2$ Total
- 2. Total degrees of freedom = NTotal 1
- 3. Total variance = $\frac{\Sigma(x \bar{x}_G)^2}{NTotal-1}$
- 4. Within samples sum of squares = $\Sigma \{\Sigma (x \bar{x})^2\}$ = Sum of Sum of squares of individual samples
- 5. Within samples degrees of freedom = Σ(Nsample -1)
 Total # of samples
- 6. Within samples variance = $\frac{\Sigma\{\Sigma(x-\bar{x})^2\}}{\Sigma(Nsample-1)}$
- 7. Between samples sum of squares = Total sum of squares- within samples sum of squares
- 8. Between samples degrees of freedom = Total degrees of freedom Within samples degrees of freedom
- Between samples variance = Between samples sum of squares/Between samples degrees of freedom

FORT = F OR T (continued)

- 10. F ratio = Between samples variance/Within sample variance
- 11. T ratio = $+\sqrt{F}$ ratio

COVAR = COVARIANCE

PURPOSE: This program calculates the necessary values for an analysis of covariance from data files stored on DECtape data tape. The paired input consists of matching files of x and y data. The output is:

- A. Number of pairs.
- B. Correlation coefficient.
- C. T value to test the correlation coefficient against the null hypothesis i.e. the correlation coefficient is not different from zero.
- D. Degrees of freedom for T.
- E. Equation of best-fit linear regression line.
- F. Sum of squared deviations of y's about the regression line.
- G. Standard error of the estimate.
- H. Sum of products xy is the sum of the cross products of x and y deviations from their respective means.
- I. Sample covariance.
- J. For the x group and the y group.
 - 1. Mean.
 - 2. Sum of squared deviations from the mean.
 - 3. Sample variance.
 - 4. Sample standard deviation.

By proper arrangement of input data the user may obtain values for each sample and for a total of all samples as a group. Sums of sample values will give the Within Samples Sums for comparison with Between Samples Sums (Total - Within Samples values) for F tests on several groups of samples. Various tests in the analysis of variance may be performed using the output of this program. The user is referred to Statistical Methods, sixth edition, by G. W. Snedicor and W. G. Cochran, Iowa State University Press, 1967, for a discussion of analysis of covariance tests.

When COVAR is called it will type "READ X LINES: ". OPERATION: The user will type line numbers of x data to be operated on and terminate line input with "CTRL/FORM". If all lines, complete data blocks, are to be used for both x and y inputs the user may type "A" for all. The program will ask for "X BLOCK NUMBERS : ", "READ Y LINES : " and "Y BLOCK NUMBERS: ". In each case, the user supplies block and line numbers and terminates input with "CTRL/FORM". Data input should be paired. The first x data point is paired with the first y data point and data blocks are read in pairs by the program so that the number of x lines to be read must equal the number of y lines and the number of x blocks must equal the number of y blocks. Unpaired data input will cause the program to type "UNPAIRED DATA" and return to the beginning. After the input of y block numbers, the program will proceed through calculation and output and return to "READ X LINES: " unless this request has previously been answered by "A" in which case the program will start over at "X BLOCK NUMBERS : ".

DESCRIPTION: COVAR will accommodate data tapes of standard (129_{10}) or shorter block length. Two complete passes of the data are done. On pass 1 the sums of x's and y's are totaled and the data is counted. The means of x and y are calculated before pass 2.

During pass 2 the sums of squared deviations from the mean and the sum of cross products of the deviations are calculated. The necessity to compute cross products demands that data be read in pairs. This program, therefore, reads a block of x data and a block of y data and then proceeds to read an x data point and a y data point.

COVAR = COVARIANCE (continued)

The following calculations are used in COVAR:

A. Number of pairs = N

1. Mean =
$$\frac{\Sigma \times N}{N} = \frac{1}{N}$$

2. Sum of Squares =
$$\Sigma (x-\bar{x})^2$$

3. Sample Variance =
$$\frac{\Sigma(x-\bar{x})^2}{(N-1)}$$

4. Sample Standard Deviation =
$$\sqrt{\frac{\Sigma(x-\bar{x})^2}{(N-1)}}$$

C. Sum of products xy =
$$\Sigma(x - \bar{x})(y - \bar{y})$$

D. Sample Covariance =
$$\frac{\Sigma(x - \bar{x})(y - \bar{y})}{(N-1)}$$

E. Correlation Coefficient =
$$\frac{\Sigma(x-\bar{x})(y-\bar{y})}{\sum(x-\bar{x})^2\Sigma(y-\bar{y})^2} = R$$

$$F. T = \frac{R\sqrt{(N-2)}}{\sqrt{1-R^2}}$$

G. Degrees of Freedom =
$$N-2$$

H. Equation of best-fit Line
$$Y' = aX + b$$

1. Slope =
$$a = \frac{\Sigma(x - \overline{x})(y - \overline{y})}{\Sigma(x - \overline{x})^2}$$

2. Intercept b =
$$\bar{y} - \frac{\bar{x}\Sigma(x-\bar{x})(y-\bar{y})}{\Sigma(x-\bar{x})^2}$$

I. Sums of Squared Deviations =
$$\Sigma(y - \bar{y})^2 - \frac{\{\Sigma(x - \bar{x})(y - \bar{y})\}^2}{\Sigma(x - \bar{x})^2}$$

J. Standard Error of Estimate
$$= \sqrt{\frac{\Sigma(y - \bar{y})^2 - \{\underline{\Sigma(x - \bar{x})(y - \bar{y})}\}^2}{\Sigma(x - \bar{x})^2}}$$
(N-2)

LCOVAR = LOGARITHMIC COVAR

PURPOSE: This program is a semi-logarithmic version of COVAR. y values are converted to \log_{ϵ} y before calculation so that each "Y" in the output format means \log_{ϵ} y. This program is useful for semi-logarithmic regression analysis.

OPERATION: Operation of LCOVAR is the same as that of COVAR.

DESCRIPTION: This program performs a linear correlation between x and \log_{ε} y. The subroutine of COVAR to read the x and y buffers, RXYB, has been altered to convert y to \log_{ε} y. Since this program is almost identical to COVAR, only the parts of the listing which differ from COVAR are given.

TPAIR = T TEST, PAIRED DATA

PURPOSE: This program performs a paired T test on data files stored on DECtape data tape. The input consists of paired files x and y data. TPAIR has the following output:

- A. Mean difference
- B. Standard deviation of difference
- C. Standard error of mean difference
- D. T value
- E. Degrees of freedom

OPERATION: When TPAIR is called, it will type "READ X LINES : ". The user will type line numbers of x data to be operated on and terminate line input with "CTRL/FORM". If all lines, complete data blocks, are to be used for both x and y inputs the user may type "A" for all. The program will ask for "X BLOCK NUMBERS: ", "READ Y LINES: " and "Y BLOCK NUMBERS: ". In each case, the user supplies block and line numbers and terminates input with "CTRL/FORM". Data input should be paired. The first x data point is paired with the first y data point and data blocks are read in pairs by the program so that the number of x lines to be read must equal the number of y lines and the number of x blocks must equal the number of y blocks. Unpaired data input will cause the program to type "UNPAIRED DATA" and return to the beginning. After the input of y block numbers, the program will proceed through calculation and output and return to "READ X LINES: " unless this request has previously been answered by "A" in which case the program will start over at "X BLOCK NUMBERS : ".

DESCRIPTION: TPAIR will accommodate data tapes of standard (12910) or shorter block length. During a single pass of the data tape the sum of the pair differences, and the sum of the pair differences

TPAIR = T TEST, PAIRED DATA (continued)

squared are computed and the number of x,y pairs are counted. The program reads a block of x data and a block of y data and then proceeds to compute using the first x point and the first y point as a pair.

TPAIR uses the following calculations:

A. Number of pairs = N

B. Difference = x - y = D

C. Mean difference = $\frac{\Sigma(x-y)}{N} = \bar{D}$

D. Standard deviation of difference = $\sqrt{\frac{\Sigma D^2}{N} - \bar{D}^2}$

E. Standard error of mean difference = $\sqrt{\frac{\sum D^2}{N} - \bar{D}^2}$

 $F. T = \sqrt{\frac{\sum D^2 - \overline{D}^2}{N}}$

G. Degrees of freedom = N-1

TPAIR 2

BCALC = BLOCK CALCULATOR

PURPOSE: This program enables the user to do calculations using data files on DECtape as variables in the calculation. Results of calculation are stored on DECtape. BCALC is a master program for handling the data files. The user must supply a floating point program, which is called by BCALC as a subroutine, for each specific calculation.

OPERATION: BCALC requires a floating point subroutine starting at memory address 3600. One page has been set aside for this subroutine. BCALC has been updated with the starting address of the tape system and subroutines are updated with a starting address of 0200. This enables the user to call the subroutine after calling BCALC and the program will begin running after the subroutine is called. If several calculations are to be done, the user may enter the tape Monitor and call the next successive calculation subroutine without recalling BCALC.

Start the tape Monitor and call BCALC and then the calculation subroutine. The program first queries the user about the block length of the data tape. Next the program will type "CONSTANT: ". After the user has typed in the first constant of his calculation and terminated the number by a non-valid floating point input (space, etc.) the program will again type "CONSTANT: ". The user should terminate the last constant input by "CTRL/FORM" which signals BCALC to go on and ask for "VARIABLE BLOCK: ". The user replies by typing the block number of the first variable in his calculation. Input is similar to the input of constants in that the last variable block number is terminated by "CTRL/FORM". BCALC will then ask "RESULT BLOCK: " and the user should type the block number of data tape in which he wishes to have the results of the calculation stored.

BCALC = BLOCK CALCULATOR (continued)

At this point the variable blocks are read into core memory, the computations are done and the results are written on data tape. Unless the program is restarted at 0200 future calculations will be done using the same constants and the program will return to "VARIABLE BLOCK: ".

DESCRIPTION: After instructions from the user BCALC reads the variable blocks into core memory. The first result is computed from the constants and first number of each variable block. The second result comes from the same calculation on the second number from each variable block. As many results will be computed as there are numbers in the first variable block.

Up to 10 constants and 11 variables may be used for one calculation.

EXAMPLE: Suppose the user wishes to calculate the values of z, where $z = ax^2$ - by and to have the z's typed out after calculation. He would write the following type of calculation subprogram to be called by BCALC.

1	Let	x	=	v ₁ ,	the first	variable
		y	-	v ₂ ,	the secon	d variable
		a		c1,	the first	constant
		Ъ	-	C ₂ ,	the secon	d constant

LCALC = LINE CALCULATOR

PURPOSE: This program enables the user to do calculations from data stored on DECtape using specific lines of a file as variables in the calculation. The result of the calculation may be stored on one line of the same file or a different file. LCALC is similar to BCALC.

OPERATION: LCALC requires a floating point subroutine starting at memory address 3600. Calculation subroutines for LCALC are identical in form to those used by BCALC and may be used with either program.

Operation of LCALC is similar to that of BCALC. LCALC asks
"VARIABLE LINE: "instead of "VARIABLE BLOCK: "and in addition
asks "INPUT BLOCK: "and "RESULT BLOCK: ". If the user wishes to
use the same result block as input block he may answer "S" to
"RESULT BLOCK: ". After the first execution the program does all
calculations using the same constants and the same lines as variables.
It returns to "INPUT BLOCK: "after execution.

"CTRL/C" will return control to the tape system index on unit #8.

DESCRIPTION: This program does one computation and produces one result per execution of the program. It is useful if data files contain nonhomogeneous data. If, for instance, the first number in each file is height; the second, weight; third, age; etc., one may wish to compute a factor which is a combination of these variables and have the result appear as the seventh number in the file. LCALC can also be used to check subroutines intended for use with BCALC.

/Call program L CALC /Call calculation subroutine EXAMP /Yes STD FORMAT ? Y /First constant CONSTANT : 10 -CONSTANT : 2(CTRL/FORM) /Second and last constant VARIABLE LINE : 1 /First variable line # VARIABLE LINE : 4(CTRL/FORM) /Second and last variable line # RESULT LINE : 15 -/Result line # INPUT BLOCK : 10 L /Input block # RESULT BLOCK : 115 /Result block # + 0.2000000E+01 /Result (will be written on line 15 / of block #11) INPUT BLOCK : 114 /Input block # RESULT BLOCK : 12 -/Result block # + 0. 2000000E+01 /Result (will be written on line 15 / of block #12) INPUT BLOCK : 10 N /Input block # RESULT BLOCK : S+0.2000000E+01 /Result block # same as input block # INPUT BLOCK : 11 /Result block # same as input block #. + 0.2000000E+01 /Same constants and line #'s for variables /And results used throughout.

INPUT BLOCK: +C /Return control to tape Monitor

INPUT BLOCK : 12 + 0.2000000E+01

```
/TERMINATE LAST CONSTANT AND LAST VARIABLE
            /WITH CTRL-FORM. RESPOND TO "RESULT
            /BLOCK : " WITH "S" IF IT IS ALWAYS TO BE THE
            /SAME AS THE INPUT BLOCK

ADDENDUM TO DECUS NO. 8-137a

Program for Storage Manipulation and Calculation of Data Using DECtape

The DECtape for this program was not generated in a PS/8-OS/8 compatible format. One may bootstrap the tape using the old Disk Monitor System DECtape bootstrap. The instructions in the write-up should be sufficient for the running of the programs on the tape once the tape is bootstrapped. The listing for the bootstrap follows:

DECtape	
Location	Content
0200 0201	7600 1216
0202	4210
0203 0204	1217
0205	3620
0206	1222
0207	4210
0210	5600 0000
0211	6766
0212	3621
0213	6771
0214	5213
0215	5610
0216 0217	0600
0220	7577
0221	7755
0222	7754
0 2 2 2	0220

Also, please note that these programs utilize the EAE hardware option.
